

Geriatric Assessment Through E-Health: Princess Alexandra Hospital GATE Program

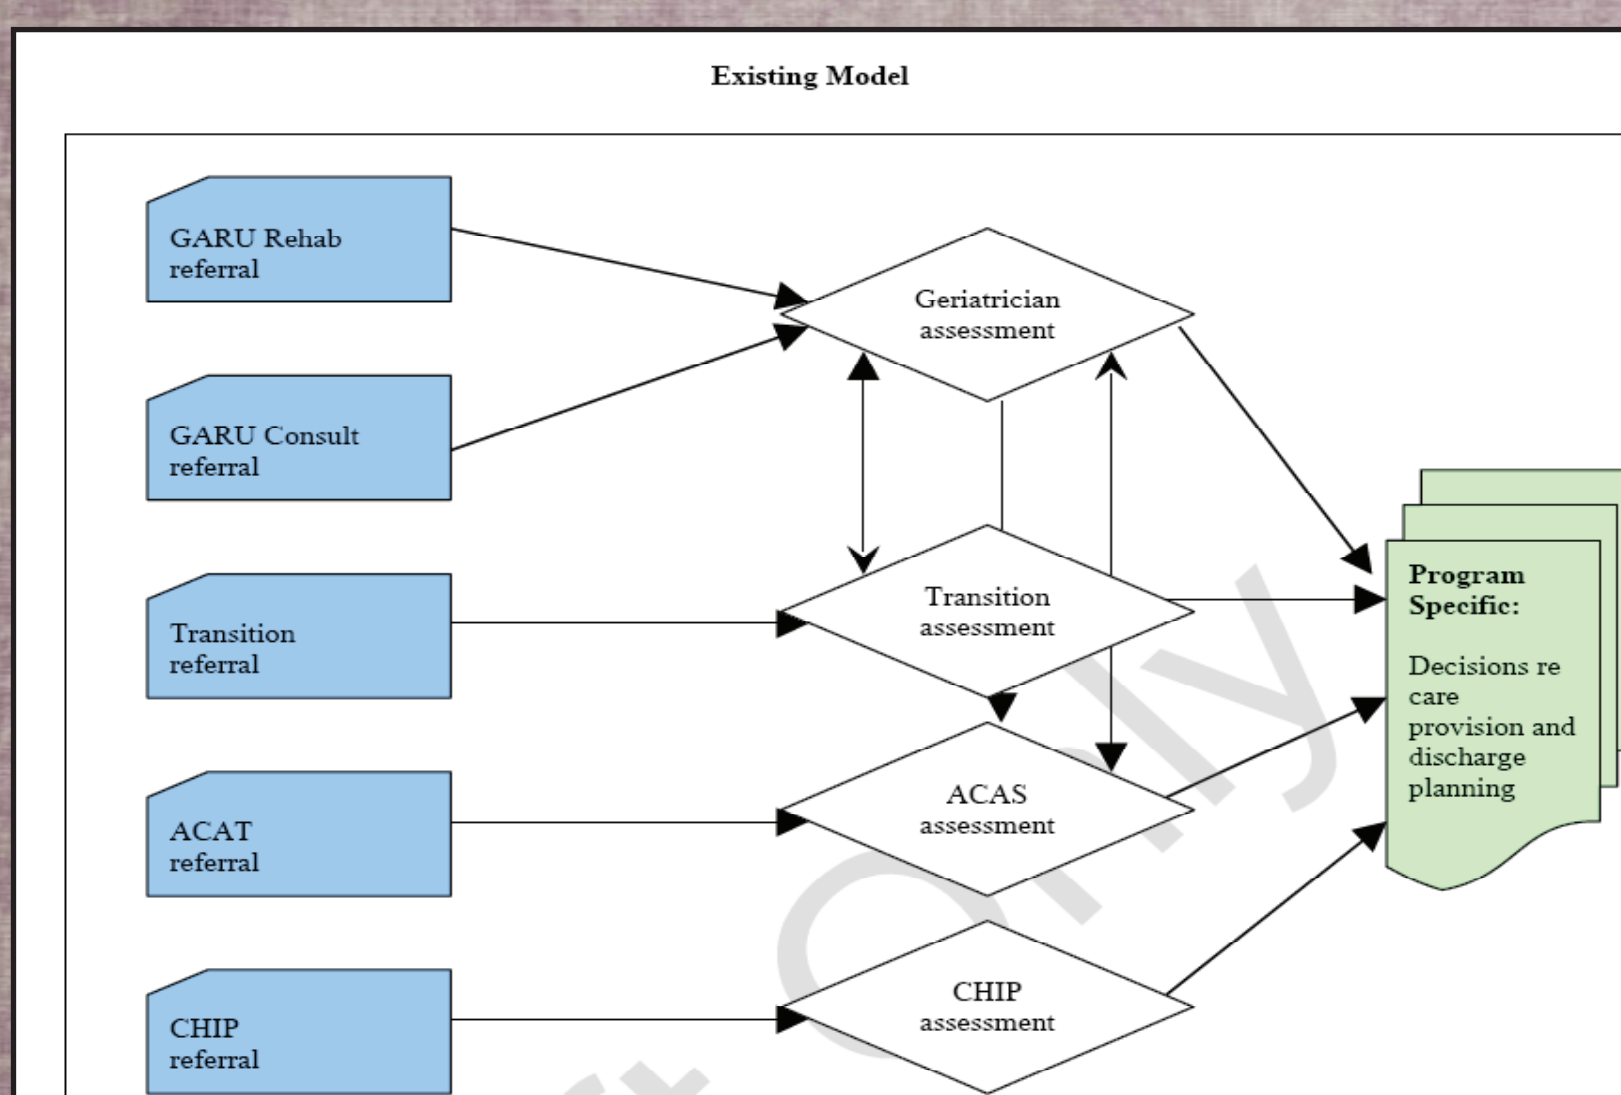

Maria Draper & Bonnie Pimm
Princess Alexandra Hospital, Brisbane

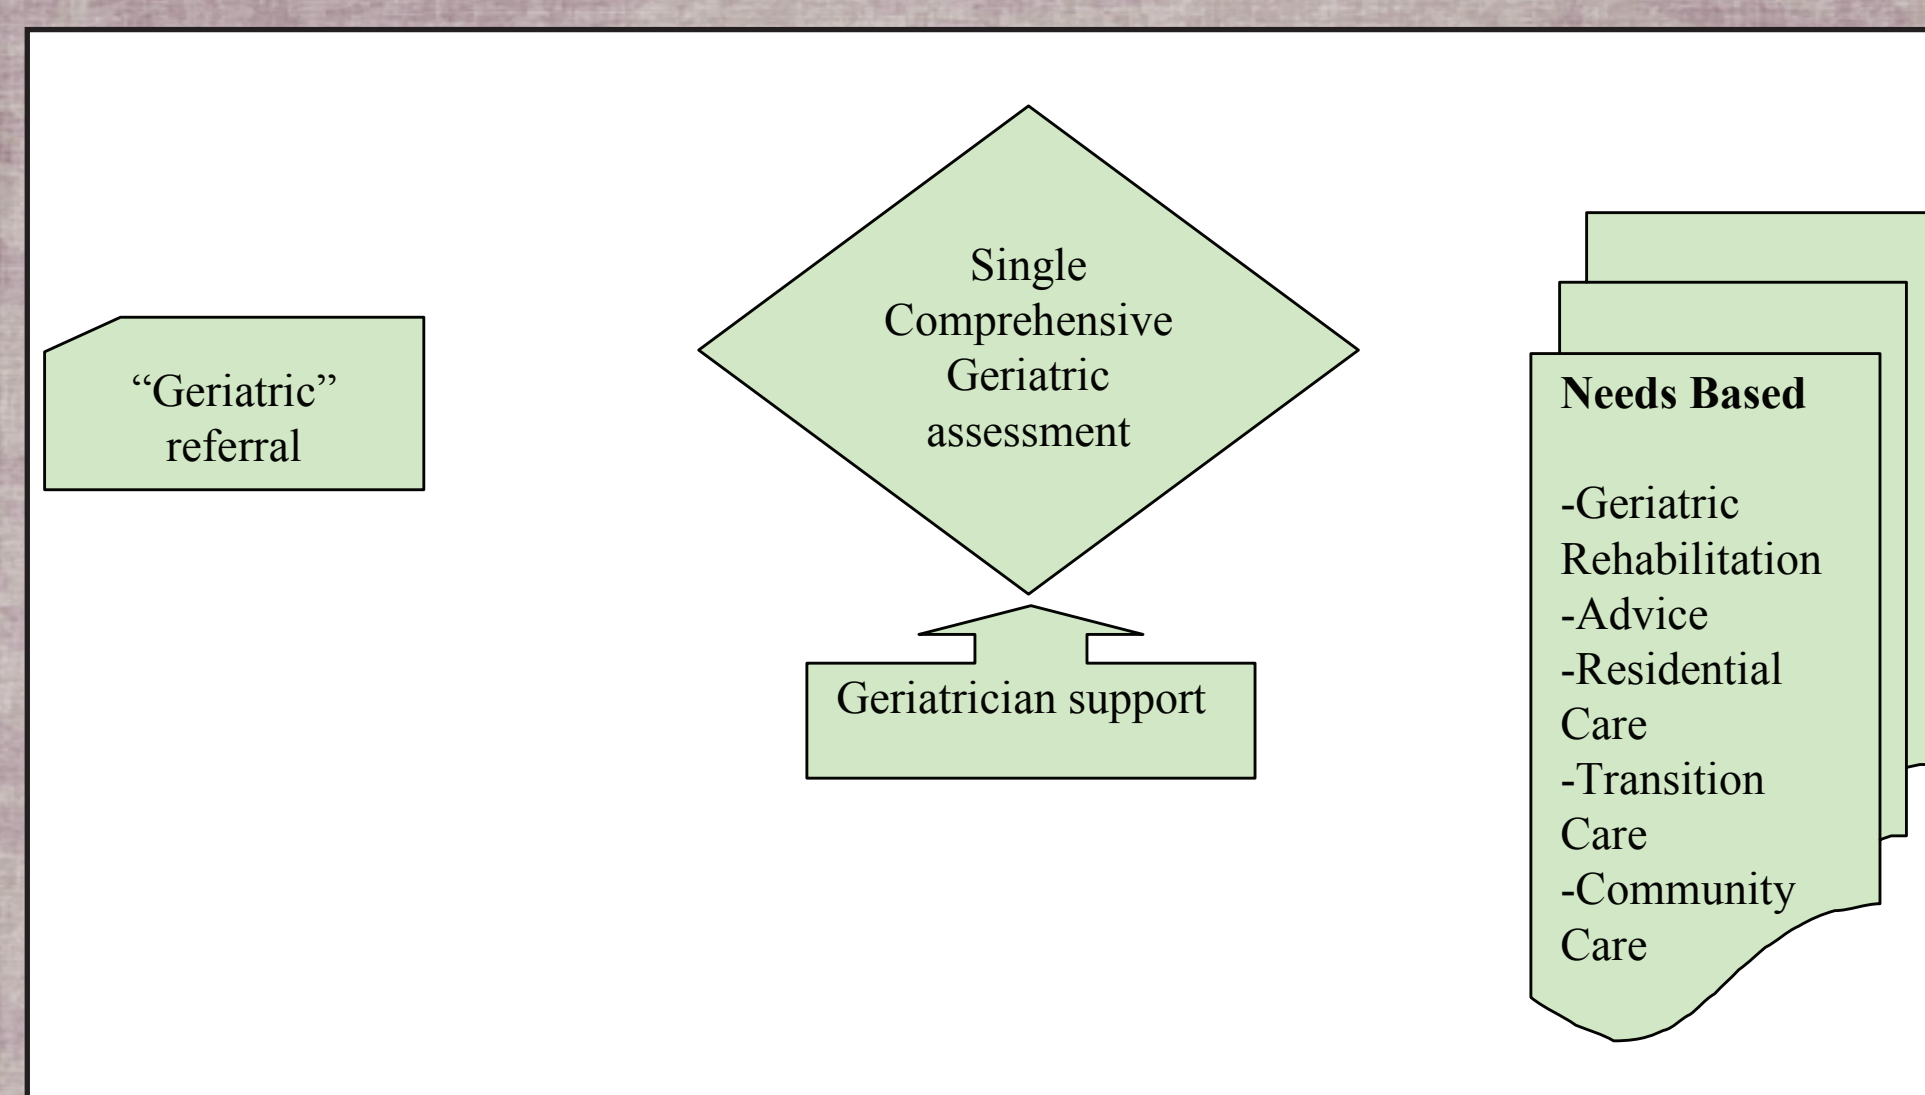

The Princess Alexandra Hospital (PAH) is a tertiary teaching hospital in Brisbane, Australia. The Geriatric Assessment Through E-Health (GATE) team have developed an innovative partnership in care delivery of aged care services using an integrated approach to geriatric evaluation and management through the use of a simplified referral and geriatric assessment process. The service now provides a single point of contact for all geriatric services, rapid triage and timely, comprehensive assessment. It was identified that the lack of a clear referral pathway for the older person in PAH had resulted in a number of inefficiencies created through delays in contacting the correct referral point, duplication of assessment and the need for cross referral from one agency to another, which in turn resulted in increased length of stay and further deconditioning of the elderly patient. The previous referral process was largely historical and reflected the development of health programs over time with the acute care setting and community services working in silos. Now a comprehensive geriatric assessment and formal geriatrician review occurs in any case referred for rehabilitation, residential care or transitional care and also on others on a needs basis (dependent on case complexity). An initial electronic report is produced within 24 hours of referral. The separations in GARU have increased by twenty five percent in two years and inappropriate referrals to ACAT are now non existent. The GATE program facilitates a smoother care path for the elderly patient and improved continuity of care.

The GATE program is an aged care assessment and liaison program that advocates for elderly patients admitted to Princess Alexandra Hospital. It addresses timely review for patients referred to geriatric rehabilitation, and for approval to residential care, and/or Transition care programs.

Previous referral pathway

Proposed Model

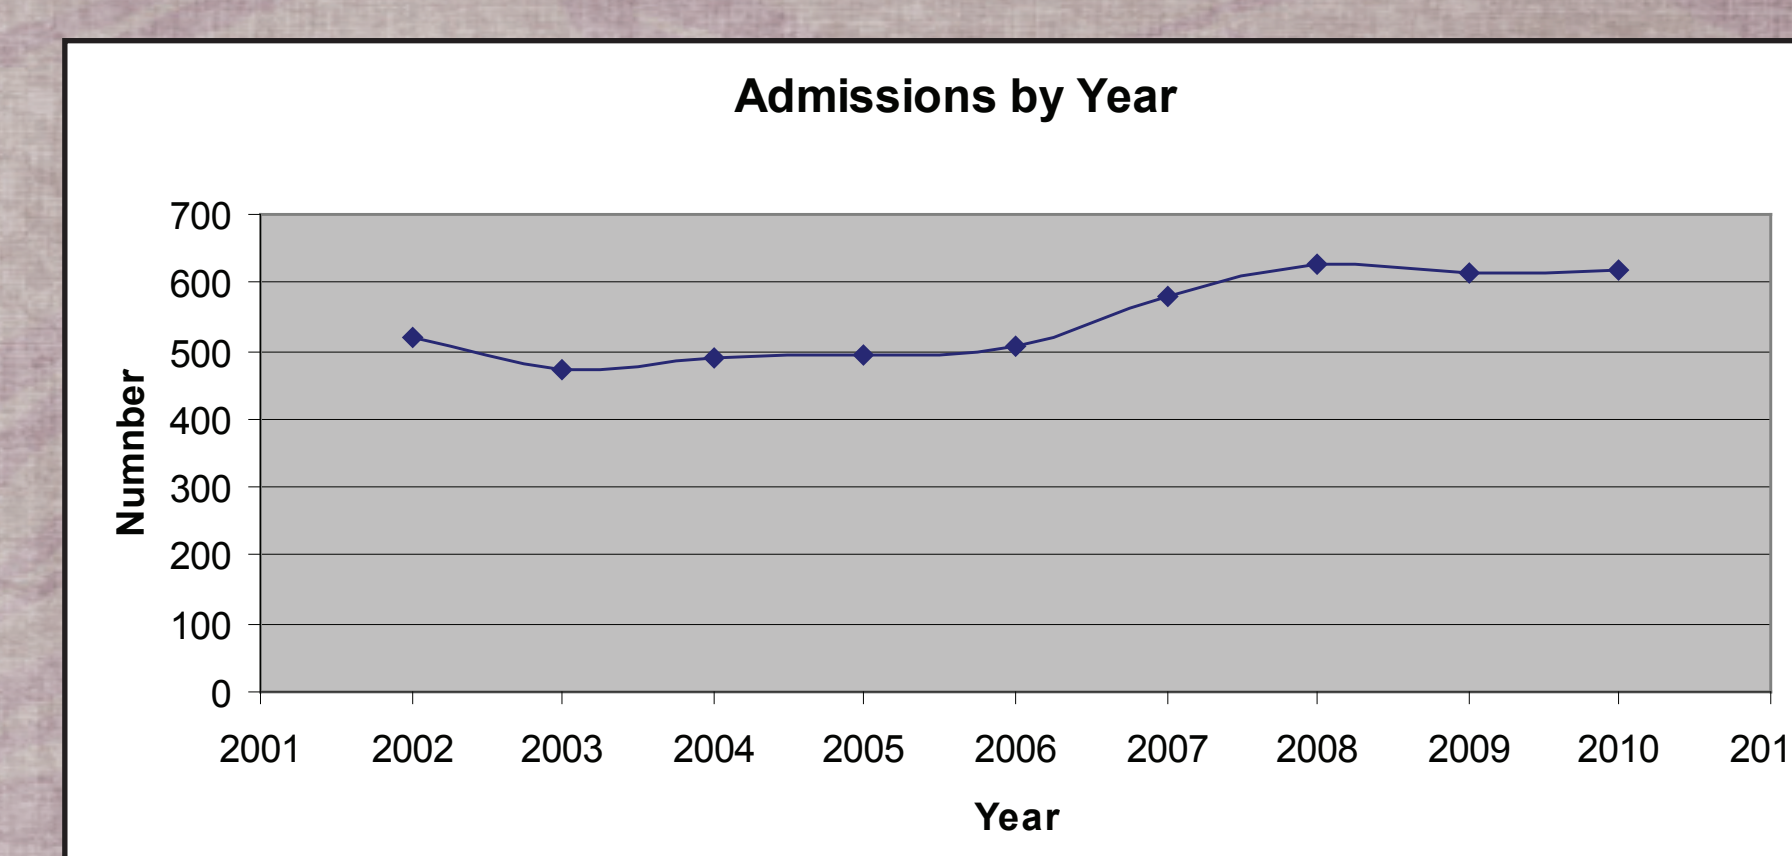

The implementation in July 2007 focused on single point of referral, Comprehensive Geriatric Assessment (CGA) of elderly patients by geriatric nurses, data entry into an electronic patient record, geriatrician review and a formal report produced for the patient records.

The clear referral pathway and early comprehensive geriatric assessment has resulted in greater than 95% of patients assessed within 2 working days of referral, an increase in patient throughput in GARU by 25% and a decrease in median LOS by 4 days while the acuity and complexity of the patients increases.

LOS

Admissions by Year

Poor referral pathways for elderly patients had resulted in delays in referrals and duplication of assessments. This resulted in increased length of stay and decline of the elderly patient. GATE has streamlined referrals and uses a comprehensive and integrated geriatric assessment for patients over sixty five to improve patient outcomes.

Attention is paid to geriatric syndrome and rehabilitation potential is explored. Elderly patients are put in right service first time and when ready. The average wait for patients on the GARU waiting list is < 2 days.

Days Awaiting GARU

Nurse assessor commentary	
Pre-morbid	Admission
At Admission by: Angela Green (Nurse assessor) Date: 26-Jun-2010 Mrs Smith was admitted on June 23 following a fall at home, in which she sustained a fracture of her L humerus. She was alone at the time and is unable to provide an explanation of the event. She was found on the bathroom floor by her daughter who was unable to get a response by telephone. She may have been on the floor for several hours. A meal had been delivered earlier in the day. She had a second recent fall when she tripped over while shopping with her daughter, but without injury. She has Parkinsons disease diagnosed 3 years ago. She has OA of both knees, which limits her mobility. She uses a walker when she leaves the house. In hospital, she became very confused, and required 1:1 nursing for the first 3 days in hospital. She continually tried to get out of bed, and her balance was poor. On day 3 a chest infection was diagnosed and antibiotics commenced. Her daughter visits her most days. She is worried that her mother is increasingly disorganised at home, not eating well, and unable to care for herself. Mrs Smith is refusing to consider alternate living arrangements.	
Disease diagnoses	
Primary diagnoses: Fractured surgical neck of humerus	
Associated active diagnoses: Bronchopneumonia	
Living arrangement and support	
Admitted from:	Private residence - owned/purchasing
Marital status:	Widowed
Living arrangement:	Alone
Support person available:	Yes
Housing available:	Yes

Cognition and mood	Pre-morbid	Admission	Review 1
Cognitive impairment (Dementia)		X	X
Delirium	nia	X	X
Behavioural disturbance		X	X
Depression and anxiety			X

Cognitive Performance Scale CPS - Max:6

Pre-morbid	2
Admission	5
Review 1	5

The use of technology and management of GARU waiting list by the GATE team has significantly improved outcomes for the elderly patients

Waiting time for ACAT assessment is now minimal. At time of this report there were only five age appropriate patients (65 years and greater) in the 600 bed acute care hospital waiting for ACAT assessment or nursing home placement.

Prior to the commencement of GATE these patients caused significant bed block. 32 % of patients referred to GATE for ACAT assessment have returned to their home.

Destination of ACAT referrals to GATE
